

## Rebuttal for ‘Guided Proofreading of Automatic Segmentations for Connectomics’

Thank you for your time and constructive comments. We will fix all minor issues.

**R2: Quantitative Evaluation** R2 requests an objective quantitative evaluation. Fortunately, our ‘automatic’ and ‘oracle’ experiments are exactly this. We define such experiments in lines 573–590 and report the results in Fig. 6, Fig. 7, and lines 792–818 (also in supplemental Sec. 2 and 3). These evaluations use the quantitative VI metric against a ground truth segmentation, with no user in the loop.

**R2: Faster than State of the Art?** ‘Faster’ here considers both how long each correction takes, and the likely VI reduction from that correction. Our approach has comparable correction time to the state-of-the-art Focused Proofreading approach, but a significantly greater VI reduction per correction (7.5×). Our presentation of this discovery could have been improved. We will add Table 1 to make this clearer (previously reported in lines 756–765, slopes in Fig. 6, and column 3 in Fig. 7).

Table 1: Average proofreading speed for users of Dojo, Focused Proofreading (FP) and our Guided Proofreading (GP). For comparable correction time, our system achieves significantly higher VI reduction per minute (7.5×) over state-of-the-art FP.

Approach	Time Per Correction (s)	VI Reduction Per Minute
<i>Dojo</i>	30.5	-0.002
<i>FP</i>	4.9	0.00023
<i>GP</i>	6.2	0.00173

**R2: Reproducibility** R2 expresses concerns regarding reproducibility. As per line 847, we have promised to release all our code and data, and we disclose all parameters.

**R2: How were Optimal Parameters chosen?** The threshold  $p_t = 0.95$  was observed to be stable when evaluating on previously-unseen test data (lines 585–586, supplemental Sec. 1.3). The **input border is dilated by 5 pixels** to consider slight edge ambiguities and to cover extracellular space between segments in high-resolution electron microscopy data (lines 308–310). During merge error detection, **labels are dilated by 20 pixels** prior to finding potential borders (line 323) with border-seeded watershed—this way the borders tend to attach to real membrane boundaries (lines 364–366). As we use a CNN, there are many additional parameters; we consider choosing these effectively to be an open problem, and for this we used learned experience and local brute-force searches.

**R3: Training Datasets—U-net vs. GP?** R3 raises the question of whether our GP approach was trained on the same data as membrane detection (U-net). There was no overlap (Tab. 2).

Table 2: Training data of membrane detection vs. training data of GP (for supplemental material).

Dataset	Training Set U-Net	Training Set GP
<i>L. Cylinder</i>	AC3+AC4 (1024 × 1024 × 175vx)	L. Cylinder (2048 × 2048 × 250vx)
<i>AC4 subvolume</i>	AC4 excl. test (1000 × 1000 × 90vx)	L. Cylinder (2048 × 2048 × 250vx)
<i>CREMI A/B/C</i>	AC3+AC4 (1024 × 1024 × 175vx)	CREMI A/B/C (1250 × 1250 × 300vx)

**R3: Merge Error Detection** R3 requests a better explanation of the merge error detection (Sec. 3.2). We have updated Fig. 4 in the main paper to be more clear (Fig. 1). We will also add pseudo code of the algorithm to the supplemental material to promote understanding (Alg. 1).

Figure 1: Merge errors are identified by generating randomly-seeded watershed borders within a dilated label segment. Then, each border is individually rated using the split error CNN by inverting the probability score.

### Algorithm 1 Merge Error Detection for a label $l$

```

1:  $l_d = \text{dilate}(l, 20)$ 
2:  $\text{invImage} = \text{invert}(\text{image})$ 
3: for N iterations do
4:    $s_1, s_2 = \text{randomSeeds}(l_d)$ 
5:    $\text{wsImage} = \text{watershed}(\text{invImage}, l_d, s_1, s_2)$ 
6:    $\text{border} = \text{border}(\text{wsImage})$ 
7:    $p = \text{rank}(\text{border})$ 
8:    $p_{\text{merge}} = 1 - p$ 
9: find(max  $p_{\text{merge}}$ )

```

**R3: GALA Active Learning Classifier** In our automatic segmentation pipeline (line 499), GALA uses a random forest classifier to agglomerate segments. While it does not require user interaction, it does require parameters. We will add a section to the supplemental material containing a full description of the approach and our use of it.
